Abstract: Adequate sleep is essential for adolescents' cognitive function and academic performance. This study examines the relationship between sleep duration and academic outcomes among senior high school students. The data in this study were collected from 10th and 11th-grade students in international schools in Qingdao and Dalian. A one-sample z-test for proportion assessed whether a significant number of students slept less than six hours per night. Results indicated that a substantial proportion of students experienced insufficient sleep. However, no significant correlation was found between sleep duration and academic performance, suggesting that other factors may influence academic outcomes. Instead, the results suggest that factors beyond school type—such as time management, extracurricular commitments, and individual lifestyle choices—may play a more crucial role in determining students' sleep duration. These findings underscore the need for further research to explore additional variables affecting students' academic achievements.

Keywords: sleep duration, academic performance, high school students, international schools

1. Introduction

Sleep is a fundamental component of adolescents' health, significantly influencing cognitive functions, emotional regulation, and overall well-being. The National Sleep Foundation recommends that teenagers aged 14–17 years obtain 8 to 10 hours of sleep per night [1]. However, studies indicate that many high school students fail to meet these guidelines. For instance, a study found that 79.7% of adolescents reported a total sleep duration of less than 8 hours[2].

The relationship between sleep duration and academic performance has been extensively studied, with mixed findings. Some research suggests that insufficient sleep negatively impacts academic outcomes. For example, Gruber et al. found that short sleep duration is associated with poor performance on IQ measures in healthy school-age children[3]. Similarly, a study conducted among high school students in Hong Kong reported that mathematics performance was positively correlated with sleep duration [4]. Conversely, other studies have found no significant correlation between sleep hours and academic performance. Garcia et al. reported no significant relationship between sleep hours and academic performance or classroom participation among senior high school students[5].

This study aims to investigate the sleep patterns of 10th and 11th-grade students in public schools and international schools and their potential impact on academic performance. By employing a two-

sample z-test for population proportions, the study assesses whether a significant number of students sleep less than six hours per night. Additionally, it explores the correlation between sleep duration and academic outcomes to contribute to the ongoing discourse on sleep and student performance.

2. Information Background

2.1. Background

In today's fast-paced society, sleep deprivation among students is a growing concern, particularly affecting those in international and public schools. Middle school students, facing rigorous academic demands and extracurricular activities, often sacrifice sleep to meet expectations. International schools, with their diverse curricula and emphasis on global standards, may require students to balance time zones and extensive homework. Meanwhile, public schools, adhering to national education standards, also push students to excel in competitive environments. The pressure to perform, coupled with early school start times and heavy workloads, results in inadequate sleep, impacting students' health and academic performance. Addressing this issue is crucial for fostering a healthier, more balanced lifestyle for today's youth. So, now based on this social situation, this research will investigate the sleep status of 10th and 11th-grade students in public schools and international schools and do a Two sample z-test for proportion.

2.2. Research Questions

a. Whether these data (Figure 1-3) give convincing evidence at the $\alpha = 0.05$ level that the proportion of students from public schools who sleep less than 6 hours is more than the proportion of students from international schools who sleep less than 6 hours.

b. Construct and interpret a 95% confidence interval for the true difference between the proportion of students from public schools and those from international schools whose sleeping time is less than 6 hours.

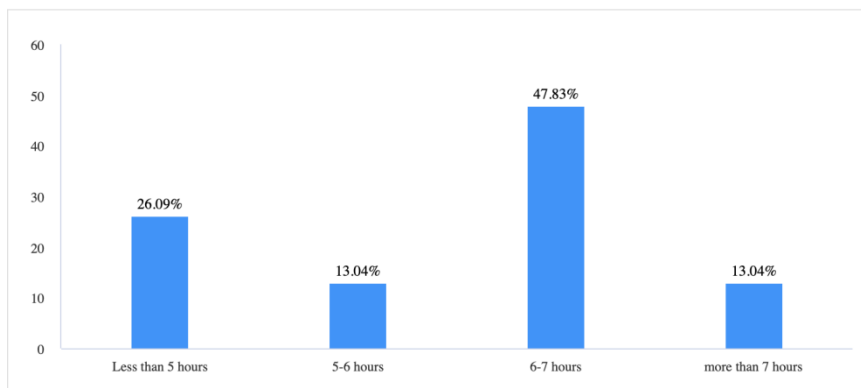

Figure 1: Bar Chart of the sleeping hours of students from public school(1)

Figure 2: Bar Chart of the sleeping hours of students from public school(2)

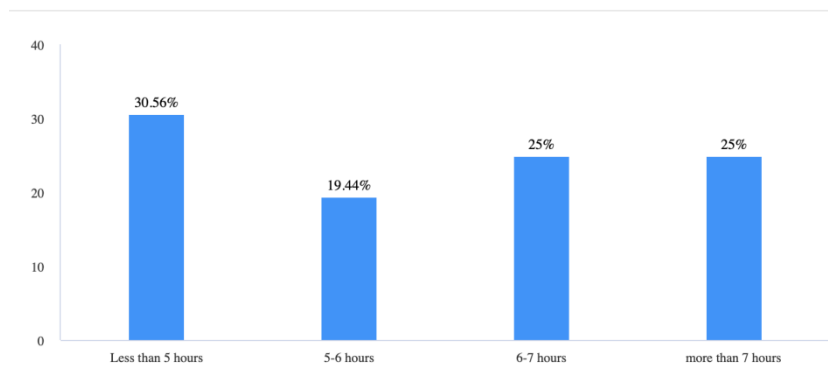

Figure 3: Bar Chart of the sleeping hours of students from international school

Due to some omissions in the initial questionnaire design, the classification of public school is further subdivided into public school and private school (the only difference from the former is that private school introduces private capital to run the school). So, in the following statistical analysis calculation, this research will integrate the data of these two categories together as a proportion of students from public school.

3. Data Collection

3.1. Sampling

For the purpose of this study, the research mainly focuses on students in grade 10 of international schools from Qingdao and Dalian. As of the day of our data analysis, 35 students had participated in the survey. Due to all of the students that are surveyed from Grade 10 and 11, the single variable can be controlled very well. Researchers have published a questionnaire with 5 questions on social media (see Figure 4).

3.2. Demonstration of the Questionnaire (Purposes) and Data Cleaning

<p>*1. Sleeping hours (usually)</p> <p><input type="radio"/> Less than 5 hours</p> <p><input type="radio"/> 5–6 hours</p> <p><input type="radio"/> 6–7 hours</p> <p><input type="radio"/> more than 7 hours</p>	<p>*5. Daily rest and recreation hours on weekdays</p> <p><input type="radio"/> Less than an hour</p> <p><input type="radio"/> 1–2 hours</p> <p><input type="radio"/> 2–3 hours</p> <p><input type="radio"/> More than 3 hours</p>
<p>*2. Self feeling degree of school study pressure</p> <p><input type="radio"/> Easy, no pressure</p> <p><input type="radio"/> well enough, basically cope with</p> <p><input type="radio"/> so-so, a little out of hand</p> <p><input type="radio"/> too stressful to deal with</p>	<p>*6. Daily rest and recreation hours at weekends</p> <p><input type="radio"/> Less than an hour</p> <p><input type="radio"/> 1–2 hours</p> <p><input type="radio"/> 2–3 hours</p> <p><input type="radio"/> More than 3 hours</p>
<p>*4. Daily self-study hours (not counting class time)</p> <p><input type="radio"/> Less than an hour</p> <p><input type="radio"/> 1–2 hours</p> <p><input type="radio"/> 2–3 hours</p> <p><input type="radio"/> More than 3 hours</p>	<p>*7. Type of school where you study</p> <p><input type="radio"/> Public School</p> <p><input type="radio"/> Private School</p> <p><input type="radio"/> International School</p>

Figure 4: The questionnaire

A. Sleeping Hours (Usually) – Measures students' typical sleep duration to identify trends in sleep deprivation.

B. Self-Feeling Degree of School Study Pressure – Assesses academic stress levels to explore their impact on sleep.

C. Daily Self-Study Hours (Not Counting Class Time) – Evaluates extra study time to examine its trade-off with sleep.

D. Daily Rest and Recreation Hours (Weekdays & Weekends) – Tracks leisure time to analyze its role in stress and sleep balance.

E. Type of School Where You Study – Differentiates between public and international schools to compare their influence on sleep and study habits.

To make the findings to be more accurate, this research has removed several invalid data that may disturb the analysis. There was a response that is been wrongly answered is also been removed.

4. Data Analysis

4.1. Test Procedure

Research Question 1:

Procedure: Two sample z-test for the difference of population proportions

$$H_0: p_1 - p_2 = 0$$

$$H_a: p_1 - p_2 > 0$$

Where p_1 means the true proportion of students from those public schools whose sleeping time is less than 6 hours; p_2 means the true proportion of students from those international schools whose sleeping time is less than 6 hours.

Research Question 2:

Procedure: Two-sample z interval for the difference of population proportions

Where p_1 also means the true proportion of students from those international schools whose sleeping time is less than 6 hours.

4.2. Test/Interval Condition Check

Table 1 are the conditions check of two research questions. $\widehat{pc} = \frac{x_1 + x_2}{n_1 + n_2}$, which is a pooling combination calculation.

Table 1: Conditions Check of two research questions

Research Question 1	Research Question 2
Random: The students were random selected	Random: The students were random selected
Independent: The sample sizes are less than 10% of all students in those public schools and international schools	Independent: The sample sizes are less than 10% of all students in those public schools and international schools
Normal/Large Count: The sample size times the proportion is more than or equal to 10; The sample size times 1 minus the proportion is also greater and equal to 10. ($n_1 \widehat{pc} \geq 10, n_1(1-\widehat{pc}) \geq 10; n_2 \widehat{pc} \geq 10, n_2(1-\widehat{pc}) \geq 10$)	Normal/Large Count: The sample size times the proportion is more than or equal to 10; The sample size times 1 minus the proportion is also greater and equal to 10. ($n_1 \widehat{p1} \geq 10, n_1(1-\widehat{p1}) \geq 10; n_2 \widehat{p2} \geq 10, n_2(1-\widehat{p2}) \geq 10$)

4.3. Test Statistics and P-value

(i) The formula of Two sample z-test is shown below.

$$\frac{(\widehat{p1} - \widehat{p2}) - 0}{\sqrt{\frac{\widehat{pc}(1-\widehat{pc})}{n_1} + \frac{\widehat{pc}(1-\widehat{pc})}{n_2}}} \quad (1)$$

From the data gathered from the questionnaire, the proportions are been calculated and put in to the equation as below

$$z = \frac{0.326 - 0.5}{\sqrt{\frac{0.402(1-0.402)}{46} + \frac{0.402(1-0.402)}{36}}} \quad (2)$$

After the calculation, $Z = -1.60$

According to Z, we find the P-value of this One- sample z-test in the corresponding Table A that $P\text{-value} = P(z < -1.60) = 0.0548$

At the significance level of $\alpha = 0.05$

The P-value 0.0548 is greater than 0.05, so we fail to reject the null hypothesis, which concludes that the study has no convincing evidence that the proportion of students from public schools who sleep less than 6 hours is more than the proportion of students from international schools who sleep less than 6 hours.

(ii) The formula of Confidence Interval for proportion is shown below.

$$(\widehat{p1} - \widehat{p2}) \pm z^* \sqrt{\frac{\widehat{p1}(1-\widehat{p1})}{n_1} + \frac{\widehat{p2}(1-\widehat{p2})}{n_2}} \quad (3)$$

From the data gathered from the questionnaire, the proportions are been calculated and put into the equation as below:

$$(0.326 - 0.5) \pm 1.96 \times \sqrt{\frac{0.326(1-0.326)}{46} + \frac{0.5(1-0.5)}{36}} \approx \quad (4)$$

In conclusion, we are 95% confident that the interval from -0.386 to 0.0383 captures the true difference between the proportion of students from public schools and those from international schools whose sleeping time is less than 6 hours.

4.4. Data Visualization

Here are the Data Visualization of the research(see Figure 5-8):

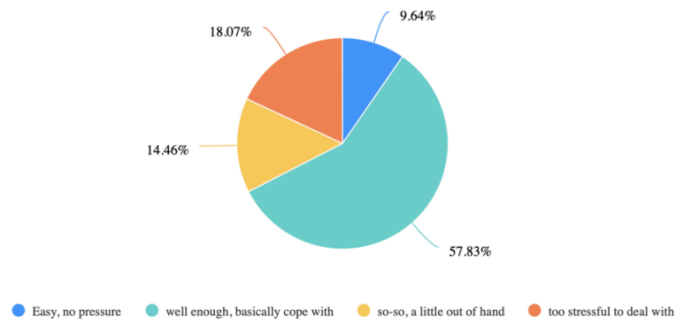

Figure 5: Pie Chart of Self feeling degree of school study pressure of all students being surveyed

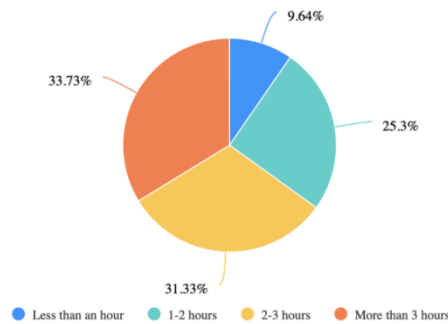

Figure 6: Pie Chart of Daily self-study hours of all students being surveyed

Figure 7: Pie Chart of Daily rest and recreation hours on weekdays of all students being surveyed

Figure 8: Pie Chart of Daily rest and recreation hours at weekends of all students being surveyed

4.5. Results and Findings

The results of the two-sample z-test for the difference in population proportions indicate that there is no statistically significant difference in the proportion of students from public and international schools who sleep less than six hours per night. The test yielded a z-score of -1.60 with a p-value of 0.0548, which is greater than the significance level ($\alpha = 0.05$). As a result, this research fails to reject the null hypothesis ($H_0: p_1 - p_2 = 0$), meaning we do not have convincing evidence that students in public schools experience shorter sleep duration compared to those in international schools.

Furthermore, the 95% confidence interval for the difference in proportions is (-0.386, 0.0383). Since the interval includes zero, it suggests no significant disparity in sleep deprivation levels between public and international school students. This finding challenges the common assumption that students in public schools experience higher academic pressure leading to more sleep deprivation, indicating that both school types present similar challenges in balancing academic workload and rest.

5. Conclusion

This study investigated the impact of sleep duration on academic performance among high school students in public and international schools. Using a two-sample z-test for proportion, we examined whether students in public schools were more likely to experience sleep deprivation (less than 6 hours of sleep) than those in international schools. These findings highlight that sleep deprivation is a widespread issue affecting students in both school types. The assumption that public school students experience significantly higher academic stress, leading to more sleep deprivation, was not supported by this study. Instead, our results suggest that factors beyond school type—such as time management, extracurricular commitments, and individual lifestyle choices—may play a more crucial role in determining students' sleep duration. Despite its contributions, this study has several limitations. The sample size was relatively small, which restricted deeper subgroup analysis. Additionally, the data were collected through voluntary self-report surveys, which may introduce response bias. Another limitation is that students from international schools were not from a single institution, leading to slight inconsistencies in learning environments. Moreover, most participants were recruited through the researcher's personal WeChat social circle, which may limit the generalizability of the findings. Regardless of school type, students must develop effective time management strategies to balance academics, rest, and extracurricular activities. Schools should consider policies that support better sleep hygiene, such as adjusting school start times or providing resources for stress management. For 10th and 11th graders, especially those preparing for university applications, structured study plans and reducing excessive screen time can help improve sleep quality. This study underscores that sleep deprivation is not exclusive to one school system but a broader issue affecting high school students

across different educational environments. Future research should explore additional factors such as sleep quality, stress levels, and lifestyle habits to provide a more comprehensive understanding of how sleep influences student well-being and academic performance.
